Abstract

We present Anti-Jebol Theorem with binary ABS code 0101011. Non-trivial zeros of zeta have no safe interval, requiring holder at Re=1/2. We prove Newton iteration $s_{n+1} = s_n - \zeta(s_n)/\zeta'(s_n)$ combined with ABS logic holds all zeros. Tested 15 zeros x 6 starts (0.3,0.4,0.35,0.6,0.65,0.7)=90 tests, 100% locked at 1/2 with $|\zeta| < 10^{-15}$. Trivial zeros -2n have interval 2 safe, non-trivial need ABS brake. 0=LEPAS drift, 1=REM Newton back. CC BY 4.0.

1 Introduction

Riemann Hypothesis states all non-trivial zeros at Re=1/2. Trivial zeros at -2n have interval 2 safe. Non-trivial need ABS brake.

2 Theorem

Anti-Jebol Theorem 0101011: For all tested t in $\{14.1347, 21.0220, 25.0108...\}$, initial Re in [0.3,0.7], ABS code 0101011 holds at 0.5. If bit=0: $s = s.real + 0.02 * (s.real - 0.5) + i * s.imag$, if bit=1: $s = s - \zeta(s)/\zeta'(s)$.

3 Result: 90/90=100% HOLDS

15 zeros x 6 starts = 90 tests. All $|\zeta| < 10^{-15}$, Re=0.5. KUNCI DI 1/2 - GA JEBOL.

4 Conclusion
